---

I wish to thank the African Economic Research Consortium (AERC) for its financial, material and academic support and for the moral support of its staff. I would like to thank the AT group of the bi-annual AERC research workshops, and the resource persons and colleagues for many helpful comments and suggestions. I express my gratitude to data collectors in the different countries in the region and the statistician at the COMESA secretariat for assisting with data. Many thanks to my family who tolerated my absence to pursue my goal of working in my continent, Africa - my husband Charles Musonda, my children, Charles, Christopher and Lilian. I am indebted to my brothers and sisters, especially Walter, who assisted me in numerous ways with data and other backstopping help. I acknowledge the great assistance of the staff in the Central Statistics Office (CSO) of Lusaka, Zambia, especially Mr. Evans Kangwa, Mr. Besa Muwele, Noah and Catherine for assisting me with data and data analysis. Two anonymous referees helped shape the work to this current structure and I am grateful. However, as the author, I alone bear the responsibility for this work, its contents and any remaining errors.

## **Abstract**

---

Using available bilateral trade data between members of the Common Market for Eastern and Southern Africa (COMESA) formerly PTA, this study estimated the extent of intra-industry trade and the factors that determine this trade in the region. The hypothesis was that intra-industry trade exists in this region. The results of the study show that indeed this trade does exist and it is determined by the same factors as found in other regions. The principal determinant is distance, which has a negative significant relationship with intra-industry trade. Other factors include per capita income and language. The trade is more significant in bordering countries that are relatively more developed in terms of their manufacturing sectors. Special ties also seem to play a role, although the variable was not significant in the regression analysis. Improved communication networks will enhance this trade within the region.

# I. Introduction

---

In pure theory of international trade, specialization based on comparative advantage is identified as the only source of international trade. However, it has become increasingly evident, based on even casual observations of trade figures, that there are large trade flows that are not related to specialization. Intra-industry trade is important, especially in industrialized countries.

Expanding trade among developing countries has been widely advocated and is normally one of the reasons for forming regional bodies. The approach that trade cooperation among developing countries (as a complement to trade with developed countries) should be based on regional integration is advocated for various reasons. Prospects for trade expansion are expected to be brighter in a regional context, since existing intra-regional trade, transport and communication links among others are closer than extra-regional links. Moreover, it is believed that cultural and historical ties make it easier to build on a regional foundation.

The purpose of this study is to establish the existence and extent of intra-industry trade (IIT) or two-way trade among the PTA/COMESA members of eastern and southern Africa. In addition, the aim is to scrutinize the likely factors that determine and thereby enhance or hinder intra-industry trade in the region. We test the factors commonly mentioned in literature that are supposed to influence this trade. Intra-industry trade is an area of study that has gained prominence, although much of the research has focused on developed countries. It has also been closely associated with regional integration and thus is a good topic for study in this sub-region.

The sub-region includes several countries with low per capita incomes as well as a few with medium level income. These countries, although they do belong to a group of developing countries, differ widely in terms of size among other factors. Among the objectives of most of PTA/COMESA is to increase trade among members. In general, the increase in intra-regional trade has not yet been as large as anticipated. It is for this reason that it is important to investigate intra-industry trade, for this may be an area where substantial benefit could be reaped if properly nurtured. Increasing this type of trade could assist in expanding overall intra-PTA/COMESA trade. It is our belief that factors determining this trade are different from those of inter-industry trade. There is thus a need for isolating those pertinent determinants, which is one of the prime objectives of this study.

The main objectives of the study are, therefore:

- To establish the existence and extent of intra-industry trade (two-way trade) between PTA/COMESA members.
- To scrutinize the likely factors that determine and thereby enhance intra-industry trade.
- To estimate the proposed regression model, assess the significance of the hypothesized determinants of intra-industry trade among the PTA/COMESA countries and explain the relevance of the results for policy making.
- To show the proportion of intra-industry trade in bilateral trade.

After this introduction, Section II discusses intra-industry trade, its definition and measurement. Section III gives the background and objectives of PTA and COMESA and the logic of studying intra-industry trade in the PTA/COMESA region. Section IV addresses the relationship between regional integration and intra-industry trade, while Section V presents the evidence of the existence of intra-industry trade in the region. Section VI shows the proportion of intra-industry trade in total bilateral trade. Section VII deals with the methodology used in the study and Section VIII gives estimation. Section IX is concerned with the study's empirical results and discussion. Finally, Section X offers conclusions and policy implications.

## II. Intra-industry trade – Definition and measurements

---

Intra-industry trade (IIT) may broadly be defined as the situation where countries simultaneously import and export what are essentially the same products. The phenomenon of intra-industry trade, which is also referred to as two-way trade within the same industry, has received increasing attention since Verdoon (1960) and Balassa (1960) found evidence of increasing IIT during the years following customs union formation in Europe. Grubel and Lloyd (1975) estimated that 71% of the increase in trade between EEC countries from 1959 to 1967 was intra-industry. Explanations for IIT have been offered, such as transport costs and seasonal differences, that are also relevant to inter-industry trade. More general exposition explaining such trade involves the aspect of imperfect competition developed into the “new trade theories”. (See also Appendix A.)

Intra-industry trade has been explained by many models. A group of such models is the neo-Heckscher-Ohlin models whose explanation is based on factor endowments by linking product specifications to different combinations of the basic factors, such as capital and labour. Here the main explanation for the occurrence of intra-industry trade is differences in the capabilities of different countries to produce more quality goods – vertical differentiations – and this is based on differences in the endowment of some of the basic factors of production.. The capital rich country will produce higher quality commodities and the labour rich country might produce the same commodity of lower quality, hence the basis for exchange of the same commodities. Another version of this class of models includes human capital as the explanation.

The other class of models explaining intra-industry trade is the neo-Chamberlinian models. In these models the explanation for intra-industry trade is that goods are “horizontally differentiated”, that is varieties differ in their characteristics and this difference may be actual or perceived. Another group of models are neo-Hotelling models. These are related to neo-Chamberlinian models but differ in terms of how they consider consumers’ demand for variety. Other models include oligopolistic models such as the Brander-Krugman model based on the Cournot duopoly model of behaviour. Yet other models includes the reciprocal dumping model where transport cost is taken into consideration, and the vertical differentiation and natural oligopolies model that takes into account the research and development expenditure for the existence of vertically differentiated products.

The models that explain intra-industry trade, while numerous, have some features in common: (1) while the models show that intra-industry trade will materialize, it is difficult to predict which country will export which commodity; (2) diversity of preferences among consumers, together with income differences, plays a significant role; (3) similarity of

tastes between trading partners plays an important role; and (4) economies of scale is an element of intra-industry trade models and may be a source of gains from this trade.

## Measurement of intra-industry trade

Many empirical works on intra-industry trade focus on the testing of models and hypotheses. In measuring intra-industry trade, a definition of an industry must be adopted. One of the criteria used to show that two different products are the output of a single industry is if it is relatively easy to substitute one for the other in the production process. Closely related to this is that the products must use an identical technological intensity. The second criterion is that different products are outputs of the same industry if the consumers of the products put them to the same use. But these two criteria can be in conflict. In measuring intra-industry trade one also needs to choose the appropriate level of disaggregation to avoid “statistical artefact”.

The first measure of the extent of intra-industry trade was proposed by Balassa in 1966. This measure is given as the extent to which exports of a given good are offset by imports of an equivalent good.

$$A_j = |X_j - M_j| / (X_j + M_j)$$

where  $X_j$  is the value of the exports of commodity  $j$  by a country, and  $M_j$  is the value of the matching imports.

However, many studies use the Grubel and Lloyd index given as

$$B_j = (X_j + M_j) - |X_j - M_j| / (X_j + M_j)$$

$X_j$  and  $M_j$  have the same meaning as above. With the Grubel-Lloyd index, when the value is zero there is no intra-industry trade and when it is one, there is perfectly matching intra-industry trade.

## Some criticism of the Grubel-Lloyd Index

Several issues can be raised in connection the Grubel-Lloyd Index in calculating intra-industry trade, despite its common use. One of the problems is classification difficulties. Many countries classify data differently, which introduces arbitrariness or randomness. This can be exacerbated by the level of aggregation of the SITC groupings. The intra-industry trade measure may be a function of the level of aggregation and thus suffer from categorical aggregation problems as it is a weighted average of the indexes for the next most dis-aggregated groups.

The classification of the commodities may suffer from downward or upward biases. Upward bias results from the heterogeneity of the commodities included in each statistical group. The downward bias stems from the inclusion of commodities with identical

technology intensity in different statistical groups. The index suffers from a downward bias if trade is unbalanced. For developing countries especially, the problem of misclassification may be important and also the issue of entrepot/re-export activities.

The Grubel-Lloyd index is a share measure – that is the share of IIT in gross trade – and not an absolute or volume measure. A high IIT is not directly connected with a high level of gross trade in the industry. A high IIT indicates that in that particular industry a high level of the given trade is of IIT nature. Some factors that explain IIT therefore explain total trade. In addition, the index does not indicate whether one should use bilateral trade or multilateral trade. This is important especially in regional trade. In many cases bilateral trade is used.

Another problem is that it is difficult to offer a precise policy implication based on intra-industry trade as calculated from the index. For example, if intra-industry trade is high, it does not necessarily imply that the country should increase its export or imports. The same applies when the intra-industry trade is low. Based on this, calculating intra-industry trade can thus be more interesting as an empirical exercise rather than for its policy implications.

### **III. The background and objectives of PTA and COMESA and the logic for studying intra-industry trade in this region**

---

The PTA/COMESA group of eastern southern and central Africa comprises about 20 countries. It started as a preferential trading area and over time its objectives and thrust widened to encompass many elements beyond the conventional definition of a preferential trading area.<sup>1</sup> The treaty establishing the PTA was signed on 21 December 1981 within the framework of the Lagos Plan of Action and the Final Act of Lagos. It entered into force on 30 September 1982. The objectives of the PTA as defined in the treaty and its protocols are:

- To promote cooperation and integration covering all the fields of economic activity, particularly trade, customs, industry, transport, communications, agriculture, natural resources and monetary affairs.
- To raise the standard of living of the people by fostering closer relations among member states.
- To create a common market by the year 2000 in order to allow the free movement of goods, capital and labour within the sub-region. To contribute to the progress and development of other African countries.

The PTA was created as a first step towards the establishment of the Common Market for Eastern and Southern Africa. The treaty for a common market for this region, COMESA, was signed in Kampala in November 1993 by the members of the PTA states and was ratified in December 1994. This was the second step; the third step will involve the establishment of an economic community.

In the 12 years of its existence, the PTA has recorded both successes and shortcomings. Among the successes is the establishment of supporting institutions. These include, among others, the Trade and Development Bank of Eastern and Southern Africa (The PTA Bank); the PTA Clearing House; the PTA Federation of Chambers of Commerce and Industry, to enable the private sector to participate effectively in PTA programmes for development; and preferential tariffs. Besides a system of national currency convertibility through the PTA Traveller's Cheques, PTA has a unit of account (UAPTA) as a medium of exchange and a common vehicle insurance through the "Yellow Card". The Customs Bond Guarantee and the Road Customs Transit Declaration facilitate intra-industry trade. To resolve trade disputes the Commercial Arbitration Centre has been set up. A PTA tribunal has also been established to settle disputes among member states arising from the interpretation or implementation of the treaty and common decisions. These PTA initiatives, together with other trade promotion and trade development activities, such as PTA trade fairs, buyers/sellers' meetings and the PTA Trade Information Network, have resulted in the creation of new intra-PTA trade.

A number of lessons have been learnt during the PTA's existence. One of these is the need to define clearly the strategy and objectives and to have a sense of direction. Another is that political will and commitment are essential factors determining the success or failure of economic cooperation and integration efforts. There are several other important elements. Intra-regional trade has not expanded rapidly because of the inadequacy of high quality goods that are competitive in terms of quality and packaging, and priced at levels consumers can afford. PTA markets are not integrated because of poor inter-state transport and communication as well as poor information about market and investment opportunities in these countries. Misapprehension about costs and benefits from PTA is another problem, as large and relatively more developed members are expected to gain more while small members are expected to gain less. This is especially true with those countries that have shown persistent surpluses in the intra-regional trade while others have deficits. These among other factors have led to the establishment of the Common Market for Eastern and Southern Africa (COMESA).

COMESA can be regarded as an offspring of the Abuja treaty signed on 3 June 1991 in Abuja, Nigeria, for establishing the African Economic Community. It constitutes one of the sub-regional trading blocs that will ultimately join together to form the African Economic Community. The overall objective of cooperation among PTA member states as outlined in the treaty is to promote sustainable growth and development through a significant increase in intra-PTA trade. The growth in intra-PTA trade is expected to have positive impact on other sectors of the PTA's economy, including finance, industry, agriculture, transport and communications. In addition, it has been decided that measures to increase production in the sub-region should constitute a primary objective. The main thrust of COMESA is to draw national economies closer by enhancing trade liberalization, facilitation, promotion and financing measures. The objective is to raise the share of intra-PTA trade to over 25% of its total trade by the year 2000. When full market integration is ultimately achieved, this share is envisaged to be higher.

All countries belonging to PTA/COMESA are categorized as developing. However, some fundamental differences exist within the group. These are shown in Table 1.

From Table 1 it is apparent that the PTA/COMESA members are diversified in terms of the basic indicators. The population of these countries varies from 52.8 million to 69,000. The land areas are also vastly different, while the GNP per capita ranges from \$5,110 to \$80. The GDP growth rate between 1980 and 1991 ranged from 8.6% to 1.0% per annum.

As mentioned above, one of the basic objectives of the PTA/COMESA strategy is to increase intra-PTA/COMESA trade to more than 25% of its global trade by the year 2000 and to a higher level thereafter. This is expected to be fulfilled after the transformation of PTA into a common market. The trade increase can be in the form of inter-industry trade (trading in commodities from different industry groups) or intra-industry trade (trading in commodities originating from same industry group). In literature it is asserted that trade liberalization following regional integration will lead to both intra-industry and inter-industry trade. However, it is advanced that the adjustment costs associated with any free trade agreement are likely to be greater when the loss of trade barriers leads to inter-industry instead of intra-industry specialization. One argument to support

**Table 1: Basic indicators of some PTA/COMESA countries**

<sup>b</sup>Implies thousands; <sup>c</sup>is the growth of GNP for 1980-1991; <sup>a</sup> is for 1987.

this is that the former type of specialization may be efficient in the long run, but it necessarily produces serious dislocation in both production and employment in the short run. On the other side, intra-industry specialization would make the adjustment cost process less disruptive because, first, it would be easier for firms and plants to cease producing a given line of goods and to start producing a closely defined variety, than to move to another type of industry. Second, changes in income distribution arising from trade liberalization would not be so dramatic under conditions of intra-industry specialization (Krugman, 1981; Wannacott, 1987; Norman, 1990).

Intra-industry studies have mostly focused on trade conducted between developed countries. Studies of the link between regional trading arrangements, and intra-industry trade includes those by Balassa (1966, 1979 and 1987), Caves (1981), Greenaway (1982), and Gavelin and Lundberg (1983), among others. Documentary evidence linking the growth of intra-industry trade to regional integration in developing countries has been provided by, for example, Balassa (1979), who found that Latin American integration (LAFTA) resulted in an increase in such trade. In fact, others have stressed that intra-industry trade is an important element in the prospects for trade among developing countries (Hughes, 1993). Hellvin (1993) analysed inter-industry and intra-industrial

specialization within the Association of SouthEast Asian Nations (ASEAN); in the case of intra-industry trade the study suggests that this trade is important.

Krugman and Obstfeld (1988) indicate that intra-industry trade is important because it produces extra gains from international trade by creating a larger market. By engaging in intra-industry trade, a country can simultaneously reduce the number of products it produces and increase the variety of goods available to domestic consumers. By producing fewer varieties, a country can produce each at larger scale and thus with higher productivity. Concurrently, consumers benefit from the increased range of choice. When intra-industry trade is the dominant source of gains from trade, the income-distribution effects will be small and there will be substantial extra gains from intra-industry trade. This is because intra-industry trade normally takes place when countries are similar in their relative factor supplies, and when scale economies and product differentiation are important. The gains from increased choice and larger scale are thus larger, as will be discussed below. Examination of whether any expansion in trade was primarily inter-industry or intra-industry in nature could provide some insights into the potential consequences of further trade liberalization (Globerman, 1992). Intra-industry trade, therefore, augments benefits obtained from inter-industry trade.

## **IV. The relationship between regional trading arrangements and intra-industry trade**

---

The literature establishes a relationship between regional trading arrangements like PTA/COMESA and intra-industry trade. Drawing on the evidence accrued from various studies, both in developed and developing countries, Greenaway *et al.* (1989) deduce that there is a causal link between intra-industry trade and regional trade arrangements. However, the theoretical analysis of the underlying mechanism is still unsatisfactory and their empirical relevance is strongly related to country-specific assumptions. Intra-industry trade may be stimulated by economic integration, but this effect is mediated by factors such as preference diversity and overlapping demand, decreasing costs in production and intra-firm trade, oligopolistic competition, and product differentiation (Behar, 1991). There are others who argue that economic integration and intra-industry trade are two phenomena that occur independently (for example, Pronfret, 1979). Another reasoning is that growing intra-industry trade as an independent phenomenon can provide a motive for economic integration (Behar, 1991). The reasons offered to explain the connection between regional integration and intra-industry trade, therefore, follow logically from the discussion of the determinants of intra-industry trade; these are discussed below.

Trading arrangements like PTA/COMESA are accompanied by the liberalization of tariff barriers among the involved economies. This trade liberalization is likely to promote trade because it is assumed that liberalization promotes trade expansion in general. A question to be answered, then, is why should economic integration stimulate intra-industry exchange to a greater degree than inter-industry exchange. It is suggested that we need to focus more closely on features of the pre-arrangement market structures (Greenaway *et al.*, 1989).

The distribution and intensity of preferences are contributory factors to the potential for intra-industry trade. If preferences are uniformly distributed across a given product, there will be a greater potential for intra-industry trade. If the pre-regional arrangement economies have like preference structures, and produce similar, but differentiated, commodities, there will be a greater inducement to intra-industry trade than would be the case with multilateral liberalization. Therefore if it is principally countries with like factor endowments, similar per capita incomes and similar demand structures that form the regional arrangement, this will be a favourable environment for intra-industry trade (Greenaway *et al.*, 1989).

The production structures and the pattern of demand existing in the preferential trading area are very important. The necessary condition for intra-industry specialization to come forth is for the production structures in individual member countries to be competitive rather than complementary. Complementary production structures may not involve

reallocation of resources within the area toward least cost producers and instead there will accrue benefits from enlargement of the market. In addition, preference of consumers can hinder intra-industry trade within the area if imports from third countries are preferred rather than locally produced goods (Drabek and Greenaway, 1984). There are cases where consumers' preferences are governed by brand image associated with foreign status (pseudo-differentiation); given this, trade liberalization may shift a country's demand for a given domestically produced product toward an imperfect substitute produced abroad by some prestigious firm (Behar, 1991).

The formation of a preferential trading area results in the reduction or elimination of non-tariff barriers. This, too, will stimulate trade expansion, directly through the reduction or elimination of these barriers, and indirectly through the reduction or removal of uncertainty.

The widening of markets resulting from trade liberalization enhances the fulfilment of decreasing costs in production. If tastes overlap, there is a benefit of decreasing costs over the relevant range of output by longer production runs and more intensive use of existing capacities (especially where excess capacity exists). The overlapping demands together with decreasing costs in the production function can encourage intra-industry trade. In addition, as income per head increases, so does the demand for variety. If forming preferential trading arrangements results in income per head rising faster than it would otherwise, then trade in differentiated goods can be expected to rise faster than otherwise.

Liberalization of capital flows can follow economic integration. Where intra-industry trade is concerned, it is likely that factor movements and trade will be complementary. Transnational corporations engaging in foreign direct investment in order to specialize in different varieties in different countries can act as the instrument of transfer. The foreign direct investment followed by intra-industry trade allows the firms to exploit the profits associated with their specific advantages, as well as providing a means for an understanding of foreign markets. This also encourages new product development and further expansion. Horizontal specialization is not the only mechanism here; vertical specialization may also be a complement factor. Firms can divide parts of the production process to take advantage of the opportunities offered by further division of labour in a larger market (Greenaway *et al.*, 1989).

Countries will therefore gain from trade liberalization, following the formation of a regional trading area, not only because this enhances trade, and thus raises the number of products available in the domestic markets. Trade liberalization also creates conditions for achieving minimum efficient scale in the new production lines, or reaping unexploited product-specific economies of scale in existing industries. Gains in the form of economies of scope would eventually be produced if the post-trade increase in product variety is due to an increase in the number of production processes observed in individual firms.

From all the factors, we can observe that there is a positive relationship between regional trading arrangements and intra-industry trade. This association is not decisive, however; it is rather that preferential trading arrangements create the environment within which intra-industry trade can increase to a greater extent than otherwise. Because of this relationship it is important to study intra-industry trade among PTA/COMESA members.

To my knowledge this kind of study has not been done because many believe that such trade does not exist in this region. It is always argued that the bulk of trade in many of these countries is on primary commodities and that they compete for developed countries' markets. Indeed, a large portion of these countries' exports is primary commodities while imports are manufactured goods from developed countries. Yet a number of the countries do trade in manufactured products within the region, in the form of both inter- and intra-industry trade. The first order of this research, then, is to establish that intra-industry trade does exist in the PTA/COMESA region.

## **V. The evidence of intra-industry trade in the PTA/COMESA region**

---

### **Data and sources**

The research required a large body of data. The data were mainly obtained from customs offices in respective countries, international organizations' publications including UN data, specifically UNCTAD publications, and other data sources in respective countries. Whenever possible we used data from respective countries as we noted that trade data reported by different countries did not tally due to the under/over-invoicing prevalent in many African countries and other problems of reporting.

### **Research Approach**

This research is carried out in two ways. First we use statistical inferences to observe in some years the direction and magnitude of intra-industry trade between PTA/COMESA members. This includes products in all SITC groups. While it is more common to take SITC 5-9 or 5-8 (manufactured products) our choice of the groups is governed by the fact that in many developing countries the value of trade in manufactured products proper may be low, but rather larger in semi-manufactured or processed products. The inclusion of this group therefore expands the sample size while at the same time ensuring the inclusion of many countries belonging to PTA/COMESA area.

Initially, the aim was to study one pre-integration and one post-integration year. However, the availability of data from some countries and the difficulty of getting data pertaining to the same year, and in addition the ambition of observing trends, motivated the researcher to delve deeper into many years. Cross sectional data across different SITC sub-sections are used for a number of years governed by data availability. Where possible we include pre-PTA and post-PTA period.

We used a regression model for estimation based on the Grubel- Lloyd index mentioned above. The model is described in detail in Section VIII.

### **Data problems**

It would be unrealistic to proceed and present the results of this magnitude without mentioning the data problems encountered. Acquiring appropriate data in some

African countries is likened to mining a very hard rock. Even after mining, there is no assurance that one will end up with the kind of mineral one was searching for; more often the reward is a large variety of ores most of them useless to say the least. In undertaking this project we encountered many problems, especially getting exactly what we needed. Because of the limited demand for very disaggregated data, it is difficult for statisticians to understand this kind of data.

Second, disaggregated trade statistics appear to pose a special problem in Africa. Many countries have stopped publishing disaggregated trade data so one either gets a computer printout that is quite large and cumbersome not to mention difficult to work with, or diskette-stored data that are in most cases unreadable. Third, many countries store their data in old and obsolete computers that even they themselves cannot read again; thus it is quite easy to lose whole years of information. The fourth and largest problem is that data obtained from different countries do not tally. For example, exports from Tanzania to Kenya should correspond with imports by Kenya from Tanzania after the required adjustments (FOB to CIF adjustment factor) have been made, but this is not the case. Maybe under/over invoicing can explain a part of the discrepancy, but we believe that data recording including different classification and categorization can explain a large part of this problem. This is evidenced by the experience of dealing with inter-industry trade, as indeed the number and trend of the applicable commodities are nearly the same, but different countries give different but close groups. Perhaps this problem will be solved after the harmonization exercise currently taking place in these countries is complete. Some countries had even different ways of classification unique to the country, but corresponding to none of the other countries until a conversion was done, (example Zambia up to 1989). Malawi's data, too, gave immense problems, as during the time considered they moved from BTN to CCCN classification then to HS. This required constant conversion.<sup>2</sup>

All these problems notwithstanding, we still calculated intra-industry trade for these PTA countries. We should mention that some countries showed no intra-industry trade; they imported or exported much to the region but imported or exported from outside the region. We therefore eliminated these countries from the outset. This is especially true with the smaller countries of the region, and those with very small manufacturing sectors.

## General observations

There is an observable interesting phenomenon pertaining to intra-industry trade flows in the countries belonging to the PTA region. This is that there appears to be a sort of specialization by trading partners. The specialization seems to be governed by proximity, including easy transport and communication, common borders and similar cultural backgrounds, and relatively similar levels of development including size. Historical ties also play a major role in enhancing this trade. It also seems that the relatively more advanced a country is, the more the intra-industry trade is caused by both demand and supply factors. Demand includes the search for variety, while supply reflects the capability of the country to produce the commodities in excess of the domestic market, thus benefiting

from economies of scale, This is evident with, for example, Kenya and Zimbabwe. The contrary is true for less advanced countries that are also small, like Rwanda, Burundi, Lesotho, Seychelles, Comoros, Djibouti, etc. Some of these countries have no intra-industry trade with any country in the region, while they import a large number of commodities from the region.

### *Intra-industry trade for Zambia*

Zambia shows large intra-industry trade with Zimbabwe, Tanzania and Malawi, and to a lesser extent with Kenya. The first three of these countries border Zambia. There is also scattered intra-industry trade with Swaziland and Lesotho but this trade is very sporadic.

**Zambia and Zimbabwe:** The two countries have a special relationship, for both belonged to Rhodesia (south and north) and thus expectedly there are relatively better developed transport and communication systems. The proximity is quite good as it takes about 5 to 6 hours to travel from one capital to another by road. The level of development is not so much in divergence if GNP per capita can be used as the yardstick; in 1991 the per capita income of Zambia was US\$ 420 while that of Zimbabwe was US\$ 650. Intra-industry trade between the two countries is large. It has grown from zero commodity groups in intra-industry trade in 1979 to 57 groups in 1987. Out of the 57 commodity groups, 45 belong to the manufactured products proper (SITC 5-8). This trend is consistent for most of the years although there is some slight increases and decreases. The year with the highest number of commodities indicating intra-industry trade is 1992. The number for 1993 does not indicate a decrease but the trade is only up to May of that year.

**Zambia and Tanzania:** Intra-industry trade between these two countries is also quite large relative to the other countries. Indeed, as with Zimbabwe, Zambia has had a special cordial relationship with Tanzania, at political and economic levels among other areas. The transport and communication systems between them are good, facilitated by the joint building of the railway line, TAZARA, an all weather tarmac road and a pipeline. Zambia has been using the Dar es Salaam harbour facilities for a long time. The countries share a common border and cultural relationship. The intra-industry trade between the two countries increased tremendously from the pre- to post-PTA period. In 1979 there were only 11 commodity groups indicating intra-industry trade and in 1981 there were 12. By 1987, the number had more than doubled to 32 groups and in 1988 there were 38 groups. A fall in 1991 is difficult to explain, since 1992 seems to have caught up. Again, the concentration of this trade is in manufactured products proper (SITC 5-8), though in many of the groups the intra-industry trade is not very high.

**Zambia and Malawi:** Intra-industry trade between these two countries is

relatively high although not to the levels of Zimbabwe and Tanzania. In 1979 there were 12 commodity groups; these grew to 18 in 1987 and 31 by 1992. The same factors as those pertaining to Zimbabwe and Tanzania can be cited for Malawi. Common border, language proximity, and especially the good transport and communication systems, are the plausible factors to explain this trade. The concentration of this trade is on manufactured commodities.

**Zambia and Kenya:** There is evidence of the existence of intra-industry trade between Zambia and Kenya. However, the number of commodity groups here is small. In 1979 there were 4 groups and in 1987 there were still 4. In 1988 they dropped to 2, but picked up in 1990 and by 1992 reached 8 groups. Although the increase is apparent and in percentage terms it is quite large – 100% from 1987 to 1992 – it is likely that these are just coincidences as there is no trend either to increase or decrease. As with trade between Zambia and Zimbabwe, Tanzania and Malawi, trade with Kenya is constrained by appearing factors. Lack of common borders between the two countries, which leads to lack of cultural relationship especially with border dwellers, difficult transport and poor communication systems are among the factors.

### *Kenya's intra-industry trade*

Kenya is among the countries that show a large amount of both inter-industry trade and intra-industry trade. One of the explanations is that Kenya has a relatively more developed manufacturing sector, and through its membership in the East African Community it easily accessed the markets of the other two countries. It could also penetrate other markets within the region with its manufactured products. Kenya indicates intra-industry trade with Ethiopia, Comoros, Seychelles, Rwanda, Burundi, Somalia and Sudan, but the trade is small and in many cases not consistent over years.

**Kenya and Tanzania:** The intra-industry trade between the two countries is large. Not only that, it seems to have grown by great leaps. In 1983 there were only 11 commodities that showed intra-industry trade, and the majority did not belong to manufactured products. This situation changed drastically; by 1991 the number of commodities had increased more than four times. The bulk of the products are manufactured and semi-manufactured goods. Needless to say, we expect this trade to increase even more in the future as Tanzania catches up with other countries in the region on trade promotion, and the manufacturing sector not only expands but is geared to exports.

**Kenya and Uganda:** There is evidence of some intra-industry trade between the two countries although not as much as with Tanzania. Surprisingly, the larger portion of this trade is shown in 1975 with 27 products, and a bigger percentage belonging to manufactured products. Thereafter, with the breakdown of the East African Community,

the number of products dropped drastically. They increased again, except in 1990 when we have only two commodities. The explanation for this is that, typical of the other countries, the transport and communication network between these two countries is relatively good. Cultural ties and language play an important role, and, in addition, both countries have a history in common. The apparent reason for the low intra-industry trade is that Uganda has a less developed manufacturing sector. Thus we find a typical example of availability being the constraining factor. Indeed, Uganda imports a very large number of manufactured products from Kenya but exports very little.

**Kenya and Zimbabwe:** One would expect a large portion of trade of intra-industry specialization to take place between the two countries because both have a relatively developed manufacturing sector as compared to other countries. However, this has not proven to be the case. Evidence indicates that in 1983 there were very few products, only two. By 1989 these products increased to 8 and in 1990 there were 9. The largest number was in 1991, with 20 products. There is only a small figure for 1992, but it may be that the data are incomplete. It seems that factors that promote trade between some countries are the same factors that hinder trade between others. Proximity seems to play a big role in this region as transport costs are great. There are high transit costs if goods have to be ferried across another country, together with other inconveniences, for example handling charges, delays, theft on the way, etc. – the number of problems is endless.

### *Tanzania's intra-industry trade.*

The observable feature of this trade as related to Tanzania is its concentration with Kenya and Zambia; the latter is explained in the Zambia section. Although Tanzania, Uganda and Kenya belonged to the defunct East African Community, the intra-industry between Tanzania and Uganda is quite small. Tanzania's intra-industry trade with Zimbabwe, Malawi, Burundi and Rwanda among others is also small.

**Tanzania and Kenya:** Intra-industry trade between the two countries is large, but was larger in 1975 during the East African Community. Here we find many commodity groups that show intra-industry - 74 in all. These dwindled to only 8 in 1981 after the break-up of the East African Community and closure of the border. The number picked up by 1989, when there were 32 groups, and in 1991 with 38 groups. Factors explaining the large intra-industry trade between the two countries are, again, good transport and communication networks, proximity, common border, language, historical ties, including the East African Common market and Community, and -especially for Tanzania- the policies instituted from 1984 including trade liberalization that have motivated individuals to expand trade.

**Tanzania and Uganda:** There seems to be quite a large amount of inter-industry trade taking place but very little intra-industry trade. This phenomenon can be

attributed to the fact that while the two countries belonged to the defunct East African Community, they both depended on manufactured products imported from Kenya. There was therefore a lack of developed market links between the two countries. It might also be the fact that Uganda lacks a developed manufactured sector. The data show that in 1975 there were only two commodities in intra-industry trade between the two countries. This type of trade did not develop over time; rather, one gets a sporadic one or two products over the years.

### *Ethiopia's intra-industry trade*

There is evidence of intra-industry trade in the case of Ethiopia. Typical of the other countries in the region, it seems that the bulk of intra-industry trade is with Djibouti. Again proximity and a special relationship play a big role. In 1988 there were 11 products indicating intra-industry trade between Ethiopia and Djibouti. In 1989 this had dropped to 9 products but in 1990 there were 12 and in 1991 there were 14 products. Kenya also shows high intra-industry trade. Other countries, including Zimbabwe, Sudan, Tanzania, Uganda, Zambia, Namibia and Mauritius, also show intra-industry trade with Ethiopia but very infrequently.

### *Sudan's intra-industry trade*

Evidence indicates that there is little intra-industry trade between Sudan and other PTA member countries. The larger proportion of this trade is with Ethiopia and quite a small portion is with Kenya. This again proves the hypothesis that many of these countries specialize in trading within the PTA region, and proximity as well as a special relationship play a big role.

### *Malawi's intra-industry trade*

Data obtained from Malawi have been presented in different ways of classification. From 1980 to 1983 the classification of the trade data was BTN. From 1984 to 1989 it was by CCCN, and since 1990 by HS harmonized system. We did not use the 1990 data as they were only up to September; the comparison with the other system was difficult and could have misled the casual observer on the actual trend of this trade. We instead decided to present the data as they were, rather than converting into SITC codes because of lack of time. In future, however, this conversion will be done. Because of the different way of classification, and given that the data were on two-digit levels of aggregation, it is not possible to compare these tables with those from different countries. Our main interest is in the trend of this trade.

Data from Malawi indicate a large intra-industry trade between Malawi and Zimbabwe. This trade was higher in the beginning of the 1980s than it was later in the decade.

Among the possible reasons for this are proximity and well-developed transport and communication systems.

Another interesting observation with the Malawi data is the intra-industry trade with Mozambique. Malawi is the first country in our sample to show high intra-industry trade with Mozambique. This trade is concentrated at the beginning of the 1980s and decreases toward the late 1980s to nearly nothing. This can be explained by the internal fighting in Mozambique especially during the mid to later part of the decade. When this trade was high, proximity seems to have played a big role. Malawi also shows large intra-industry trade with Zambia, which was discussed with the Zambian data. Tanzania and Kenya also contribute to Malawi's intra-industry trade. Some other countries also show a little intra-industry trade in some years, including Swaziland and Lesotho.

### *Zimbabwe's intra industry trade*

The data available to us show that Zimbabwe is one of the countries in the PTA region that exhibit a very high level of intra-industry trade with many countries. The countries include Malawi, Zambia, Mozambique, Tanzania, Kenya, Swaziland, Ethiopia, Sudan, Angola and Lesotho. We have detailed data for Zimbabwe for only 1991 and we observe that in intra-industry trade between Zimbabwe and other PTA countries the highest number of commodities are found between Zimbabwe and Zambia. As explained in the Zambia section this is not surprising since the two countries are neighbours connected with a good transport system; in the past they were one country and they share a border. Zimbabwe and Malawi data give 83 products, while between Zimbabwe and Mozambique there are 81 products. These two are neighbouring Zimbabwe and again have good transport systems. Kenya shows 41 products, Swaziland 24, Mauritius 18, Lesotho 8, Tanzania 6, Angola 4, Namibia 5, Sudan 1 and Burundi 1. An interesting observation is that most of the goods in the intra-industry trade between Zimbabwe and the rest of the PTA/COMESA countries are manufactured products.

### **Evaluation of the empirical findings**

A number of observations can be drawn from these collected data. Intra-industry trade does exist between these countries of the PTA/COMESA region. However, the trade is concentrated in certain countries as shown above. The levels of the trade are low as compared to advanced countries and even the more advanced developing countries. In 1984, intra-industry trade between NICs was 22.1% while that between LDCs was 12.0%.<sup>3</sup> This trade is much higher between developed countries, depending on the category. We explained earlier the determinants of intra-industry trade and its connection with economic integration. We noted that theory predicts that intra-industry trade is determined by demand and supply factors, including similarity in tastes between the trading partners. The extent of trade overlaps between potential trading partners is important in explaining this trade. Other factors include decreasing production costs, scale economies, entry

conditions and entry barriers, for example, quantitative restrictions, transport costs, natural trade barriers, product differentiation, special relations, etc.

Before we give the empirical results, logical reasoning and casual observations indicate to us that in these PTA/COMESA countries some of these factors seem to be the main influence of intra-industry trade. The main factor is proximity. It seems that communication and transport problems in these African countries compel them to trade with their next-door neighbours. However, since the neighbours may be many, it also seems that countries of similar levels of development and size have higher levels of this trade. This is connected to tastes and preferences; that is, countries that are at the same level of development will exhibit more similarity in taste and therefore show higher intra-industry trade. In addition, data suggest that many of these countries tend to have a sort of specialization as to whom to trade with through special relationships. A good example of this is Zambia and Tanzania. Indeed, it is perhaps the special relationship that motivates these countries to develop or improve their communication and transport networks. The observations from these countries agree with what theory predicts, especially with some factors that can be easily picked up. Smaller countries seem to have very little intra-industry trade and perhaps scale economies or lack thereof can explain this. One of the powerful results is that intra-industry trade does exist in these countries, problems of data notwithstanding. It is not clear whether the formation of the PTA has increased this trade, although there is some evidence in some countries, notably between Zambia and Tanzania and between Tanzania and Kenya. It is difficult to attribute the increase to regional integration, since many of these countries have adopted a variety of policies since the mid 1980s that have also influenced intra-PTA trade.

## VI. The proportion of intra-industry trade in total bilateral trade

The proportion of intra-industry trade in total bilateral trade in the PTA sub-region is shown in Table 2. This is given for selected countries and selected years to offer detail of this trade.

**Table 2: Intra-Industry Trade as ratio of total bilateral trade and the average share of IIT for some countries in the PTA/COMESA region 1991**

Zimbabwe with	Ratio of IIT in total	Average IIT	Kenya with	Ratio of IIT in total	Average IIT	Zambia with	Ratio of IIT in total	Average IIT
Angola	32.24	9.05	Ethiopia	3.4	36.0	Angola	-	-
Kenya	19.1	45.5	Malawi	72.0	17.7	Botswana	28.76	34.76
Lesotho	22.5	37.4	Mauritius		0.36	Egypt	-	-
Malawi	48.1	22.2	Mozambique		24.71	Kenya	-	-
Mauritius	10.4	21.7	Rwanda		11.23	Malawi	64.14	21.86
Mozambique	40.6	19.4	Seychelles		14.01	Namibia	41.70	23.92
Burundi	-	10.8	Somalia	0.29	55.43			
Ethiopia	36.4	52.9	Sudan	4.83	9.34	South Africa	22.88	18.23
Namibia	9.3	15.3	Tanzania	31.02	31.1	Swaziland	0.3	16.33
Sudan	1.78	3.53	Uganda	6.42	26.31	Tanzania	72.24	25.31
Swaziland	19.5	16.6	Zambia	7.73	16.9	Zaire	-	-
Tanzania	27.73	4.33	Zimbabwe	16.0	32.97	Zimbabwe	29.52	27.61
Zambia	54.74	19.91	-	-	-	-	-	-

Source: Calculated by the author using data from CSO Zambia and COMESA Secretariat.

Table 2 shows that the ratio of intra-industry trade in total bilateral trade is high for some countries for Zimbabwe and Zambia it is over 50%, likewise for Malawi and Mozambique. Zimbabwe in 1991, has a high number of countries that show intra-industry trade, ranging from 54.74 % with Zambia to 1.8% with Sudan. One interesting observation is in order here and that is that the countries that border Zimbabwe also show a relatively higher intra-industry trade component of bilateral trade, further confirming the empirical observations above. Kenya shows a high ratio with Malawi and Tanzania. Zambia's data show a high ratio with Malawi, Tanzania and Namibia. The average level of the index of IIT differs among the bilateral partners but overall it is below that of developed countries. Zimbabwe's IIT for the year 1991 ranges between 53% with Ethiopia and 3.53% with Sudan, while Kenya's ranges between 55% with Somalia and 0.36% with Mauritius.

We present further data for the ratio of IIT in bilateral imports and exports in Appendix B because in many cases the variation is quite large. An average of all countries will

obstruct the uniqueness shown by different countries. This is calculated as the sum of those exports appearing in intra-industry trade and divided by total exports to that country for exports and the sum of those imports appearing in intra-industry trade and divided by total Imports from that country for imports. As expected, results are only for selected countries since some countries do not have any significant intra-industry trade. A country like Rwanda, for example, may show one entry of intra-industry trade occasionally but with no distinct pattern.

From Table B6 in the appendix, we observe that the proportion of intra-industry trade in total bilateral trade is very high in some cases. In 1991, intra-industry trade between Kenya and other PTA countries indicates a very high proportion in imports. For Sudan it is 99.6%, Ethiopia 93.6% and Uganda 88.8%; Tanzania is medium at 46.9%. For exports, the highest is with Zimbabwe (46%) followed by Tanzania (27.6%). These results say that most of the imports from Sudan, Ethiopia and Uganda are two-way products. This can be explained by the fact that Kenya is relatively more industrialized compared with these other countries, thus whatever importation takes place, it is quite likely that the commodities are available in Kenya as well, though different from the exports with the same countries whose intra-industry proportion is low.

In intra-industry trade between Zimbabwe and other PTA countries in 1991, we see that for imports, the highest is with Angola (87.7%), then Sudan (77.8%), followed by Ethiopia (75.6%), Zambia (66.7%), Malawi (60.5%), and Tanzania (47%). A high level of Zimbabwe's imports from these PTA countries is in two-way tradeables. For exports, Swaziland shows 93.1% of the proportion of intra-industry trade in total bilateral exports. Zambia also gives a high proportion (51.7%) while Malawi gives 47.2% and Mozambique 40.1%. (See Appendix C for a summary of intra-industry trade for Zimbabwe and Kenya).

Intra-industry trade between Zambia and other countries shows that, for 1990, the high proportion is with Malawi (60.8%) for imports, while for exports it is with Lesotho (85.7%). This pattern is repeated for 1992, with imports from Malawi indicating 30.4% and exports 87.7%. For Zambia also, the proportion of intra-industry exports in 1992 is quite high for all countries reported. For 1993, exports to Zimbabwe are high at 98.9%. However, the figures for 1993 are only up to May of that year.

Malawi is not directly comparable to other countries since here the data are for two-digit classifications. However, an indication is in order, and we observe that the proportion of intra-industry trade in total trade is high with Zimbabwe for both imports and exports. Tanzania shows a high level of intra-industry trade with Malawi's imports.

Refer to Appendix D for trade categories and Appendix E for summary tables of intra-industry trade for selected PTA/COMESA countries.

## **VII. Methodology and hypotheses explaining intra-industry trade**

---

Empirical studies of intra-industry trade are few. Balassa (1986) investigates this trade in developing countries, among others. He uses country characteristics including average per capita income, income inequality, average country size, inequality in country size, trade orientation, distance, border and common language variables. The hypotheses put forward are supported in many of them, although some are not significant. Hellvin (1993) provides another empirical study for Asian countries. The variables included are both country and industry specific, although the final report concentrates on country specific-variables. The result of the study is that only distance and tariffs are significant. In this study we concentrate mainly on country variables.

The extent of intra-industry trade in an industry is expected to be larger the higher the degree of scale economies in that industry. If differentiated goods were produced with constant economies of scale, each variety could be produced domestically and no intra-industry trade would take place. With economies of scale, each firm specializes in production of a specific variety in order to take advantage of the economies of scale in production. Countries specialize in production of a few varieties and exchange these by trade in order to satisfy the demand for variety. Many studies, especially in developed countries and a few in developing countries, proxy economies of scale with minimum optimal scale as percentage of consumption, or other scale efficiency measures. (see Behar 1991, among others). However, it is difficult to get a minimum optimal scale for many of the countries belonging to PTA/COMESA, and calculating for all these countries will take us out of the scope of the study, not to mention the time limitation. In addition, casual observations of the trend of this trade in these countries suggest that country-specific characteristics are more important.

Product differentiation in an industry also affects the extent of intra-industry trade in that industry; the higher the degree of product differentiation, the larger the trade. As explained above, intra-industry trade occurs in differentiated commodities. If domestic industry is not able to produce all potential varieties, theoretical analysis shows that the number of available products will probably be larger when countries engage in trade and in this respect regional trading will enhance this effect. There are two fundamental types of product differentiation: horizontal and vertical. The former refers to differences in product characteristics primarily related to style. The latter refers to differences primarily related to quality. In empirical models product differentiation can be measured by the coefficient of variation of export unit values to diverse destination (Hufbauer index) among other methods. The greater the coefficient, the larger the extent of product differentiation. Another approach is to interpret large percentage differences between

unit values of imports and exports as an indication of vertical specialization. Others use research and development (R&D) expenditure, while others use advertising to sales ratio (Clark, 1993). While all these measures are important, we note that research and development are quite minimal in many of the countries we are interested in and likewise advertising; in addition, information pertaining to expenditure on research and development and advertising is not readily available. In general, we concentrate on the country characteristics rather than the industry characteristics following the example of many who have dealt with multi-country studies based on developing countries, for example Balassa and Bauwens (1987) and Lee and Lee (1993).

We employ a regression analysis to ascertain the significance of the factors frequently mentioned in theory that are supposed to explain intrase factors include the level of per capita incomes, differences in the per capita incomes, the average country size, the similarity/differences in the country sizes, income overlap, the distances between the countries, scale economies, product differentiation and average levels of trade barriers. In addition to these factors and in particular for these PTA/COMESA members, we can include a variable that will take care of countries that had/have special economic relationships. It is reasonable to assume that if two countries have a special relationship – economic, political, etc. – it is more likely that a relatively larger trade including intra-industry will take place than in those without. For instance, trade between Kenya, Tanzania and Uganda might be higher compared with other PTA/COMESA members as these countries used to belong to the now defunct East African Community and this ensured that they had better linkages in many areas.

## The model

We used a regression model for estimation based on the Grubel-Lloyd index, which is normally used to measure intra-industry trade:

$$IIT_{jk} = 1 - \left( \frac{\sum_i X_{jki} - M_{jki}}{\sum_i (X_{jki} + M_{jki})} \right) * 100 \quad (1)$$

The value of IIT shows the extent of intra-industry trade and is used as the dependent variable. The country-specific variables as discussed above are used as independent variables. The method used is a cross-country test of determinants of intra-industry trade between members of PTA/COMESA. Those countries that did not indicate any intra-industry trade were excluded, as were those for which we could not get information. According to Equation 1 the dependent variables lie within the range of (0,100), depending on the importance of intra-industry trade. To ascertain that the predicted values are also limited to the interval, a logistic function is employed and non-linear least squares that permit inclusion of extreme values (Balassa, 1986; Balassa and Bauwens, 1987; Lee and Lee, 1993). The non-linear least squares method has the advantage of permitting the inclusion of zero observations.

This is specified as

$$IIT_{jk} = 1/[1+EXP^{-\beta Z_{jk}}] + e, \quad (2)$$

where  $Z_{jk}$  is the vector of explanatory variables,  $\beta$  the corresponding vector of coefficients, and  $e$  is the disturbance term.

The explanatory variables, which are country characteristics, include APC, the average level of per capita-incomes; SAZ, the average country size; and the DIS, distance between countries. TB is trade barriers, DPC is dissimilarity in per capita income, D1 is a dummy variable to take into account the special relations, D2 is a dummy variable to take into account countries with common borders, and D3 is a dummy to take into account common language.

The extent of intra-industry trade between countries is hypothesized to be larger/smaller the higher/lower the average level of their per capita-income. The positive relationship between level of development and the level of intra-industry trade is explained by a high per capita income, which is interpreted as a high ratio of capital-labour endowments. Countries with high per capita income are expected to be more endowed with capital. Assuming differentiated goods to be more capital-intensive in production than homogeneous goods, production of differentiated goods will then increase with capital endowments.

The share of IIT will be negatively related to the dissimilarity in per capita incomes. A similar level of per capita income represents a similar demand structure. Similarity in per capita incomes will influence preference and overlapping demand, which will increase intra-industry trade. Disparate per capita incomes imply less IIT.

The extent of intra-industry trade between two countries is expected to be larger/lower the larger/smaller their average country size. Differentiated commodities are assumed to be produced with economies of scale. A country with a small domestic market has a limited opportunity to take advantage of the economies of scale in production. The likelihood that domestic firms are exploiting all extant economies of scale is greater, other things being equal, the larger the size of the domestic economy. For small countries, the domestic market by itself may not be able to seed plants of minimum efficiency in scale. Hence, the larger the domestic market, the larger the potential for production of differentiated commodities and the greater the opportunity for intra-industry trade.

Barriers to trade reduce competitive pressures and hence the incentive to cut costs. Where domestic producers are not exploiting all extant economies of scale, increased competitive pressures should encourage efforts to improve efficiency. In this regard, trade liberalization of product flow is expected to encourage IIT by stimulating competition within domestic industries.

Distance shipped is another important factor. Intra-industry trade is expected to be higher for commodities that have lower transportation costs. In many empirical studies of intra-industry trade, distance has been hypothesized to have a negative impact on the

share of intra-industry trade. It is assumed that the consumption of differentiated goods requires more information than consumption of homogeneous goods. In addition, given that we are concerned with developing countries characterized by inadequate development of their intra-regional infrastructure, the longer the distance, the more direct transportation cost and more inconveniences including uncertainties – thus less intra-industry trade. It is thus hypothesized that the extent of intra-industry trade will be negatively correlated with the distance between countries.

Familiarity with each other's products contributes to increased intra-industry trade between countries. Common language is a vehicle towards this familiarity, as is the existence of past colonial ties. This gives us the hypothesis that the existence of a common language increases the extent of intra-industry trade between countries.

The existence of common borders also contributes to information flows. Grubel and Lloyd (1975) suggest that in countries sharing a common border, intra-industry trade may take place in products that are functionally homogeneous but differentiated by location. Hence we hypothesize that the extent of intra-industry trade will be higher between countries that share a common border than otherwise.

## VIII. Estimation

---

The parenthetical information in Table 3 explains how the particular variable will be measured. The justification for the choice of these variables is that most seem to be representative and are, moreover, commonly used in empirical studies of this nature. We also include other variables that might be important as we observe the data from these countries.

**Table 3: Variables used in our study: What they are expected to measure, expected signs and hypotheses**

Variable	Aimed to measure (how measures)	Expected sign	Hypotheses
APC	Average per capita income (GDP per capita)	Positive	The lower the average per capita income the smaller is IIT and vice versa
SAZ	Average country size (level of GDP or population)	Positive	The larger/smaller the average country size, the higher/lower the IIT.
DIS	Distance (kilometres between capitals)	Negative	The larger the transport costs, the smaller is the IIT
DPC	Dissimilarity in per capita income (variation in per	Negative	The more dissimilar the per capita incomes the lower the IIT and vice versa
TB	Trade barriers (tariffs and frequency of QRs.)	Negative	The higher the average level of level of trade barriers, the smaller the IIT
D1	Dummy for common language (English)	Positive	The extent of IIT is expected to be larger if the countries share common language
D2	Dummy for special relations	Positive	The closer the special relations the higher the IIT
D3	Dummy for common border	Positive	The shared border increases the likelihood of higher IIT

## **IX. Empirical results and discussion**

---

The empirical estimates for some PTA/COMESA countries are reported in Table 4. The sample includes those countries that portrayed IIT and those for which we managed to obtain information. These countries are Tanzania, Zambia, Kenya, Zimbabwe, Malawi, Ethiopia and Sudan. However, for independent variables, we included all countries in the PTA/COMESA region.

Table 4 indicates several features of intra-industry trade in PTA region. The estimations are for the year 1991, as we had consistent data for most of the variables for the year. The results support the hypotheses put forward regarding country characteristics as far as expected signs are concerned. We dropped the variable DPS, which was to take care of dissimilarity of tastes because it was highly collinear with that of APC indicating per capita incomes. All variables came out with correct signs. However, in terms of significance of the variables, it is only DIS that is significant at 1% level. For the estimation of this variable we used the distance between two trading capitals, and the actual distance of roads connecting the two capitals. The two gave almost the same results. We even tried with actual cost of shipping the goods but more complications on this variable arose due to the issue of handling and delays, which are different for different areas. Apart from that, different goods command different prices especially if they are in bigger or smaller loads. This variable proves that indeed distance plays a big role in reducing the level of intra-industry trade between these countries. The level of tariff protection came out with correct negative sign in most cases but it is not significant, which suggests that in these countries factors other than tariff levels obstruct trade. These factors include the level of income, here indicated by per capita income, which came out significant at 5% level. The population level, which is a proxy for size of the countries, is also supported. The language dummy, which is 1 for English speaking and 0 otherwise, is weakly supported at 5% level. The other variables are not significant.

We also experimented with manufactured value added of different countries belonging to COMESA and we observed that manufactured value added is significant and positive. This indicates that the availability of manufactured goods to trade with each other is important. The dummy variables indicating shared border, special relations and common language (we took English for common and otherwise zero) are weakly significant and only when they are regressed separately. This might indicate that there is a correspondence between these dummies. For example, it is more common for countries sharing the same borders to have special relationships including the same language.

The results obtained by logit estimations are supported by these by non-linear

**Table 4a: Results for country variables (logit estimation)**

Variable	Expected sign	Equation 1	Equation 2	Equation 3	Equation 4

D 3	Positive	6.8(1.6)	4.03(0.87)		
Number of observations	118	118	118	118	
		R <sup>2</sup> = 0.26	R <sup>2</sup> = 0.26	R <sup>2</sup> = 0.24	R <sup>2</sup> = 0.21
		D.W = 1.7	D.W = 1.65	D.W = 1.65	D.W = 1.64

estimations. The non-linear estimates give us R<sup>2</sup>, which is about 0.26, implying that the explanatory power of the variables is only 26%. However, this result is plausible given that the explanation for the existence of intra-industry trade in these countries is difficult to establish because of the randomness of their trading. The year-to-year variations of intra-industry trade in the region are quite large.

Overall the results from our estimation concur well with those of the other studies noted above. In most of the studies, distance gives negative and significant results, which agrees with our findings. This is the same with many other variables, indicating that intra-industry trade in the region is determined by common variables pertaining to other countries.

The empirical support in our study is smaller than other studies especially those conducted in developed countries because of the presence of domestic distortions caused by inward-oriented regimes in many of the countries in our sample. Many hypotheses

that have been tested are generated from models that are based on assumption of efficient markets, an assumption that is not satisfied in our countries of concern. However, the presence of these distortions is manifest in the low level of intra-regional trade for these countries so that the distortions are already apparent. The regression analysis is also constrained by the poor quality of data pertaining in these countries.

## **X. Conclusions and policy implications**

---

As stated at the beginning of this report, the aim of the study was to investigate intra-industry trade in the PTA/COMESA sub-region. This study has attempted to show, from the data available, that the countries belonging to this sub-region do engage in intra-industry trade especially with their immediate neighbours, and those that are relatively more advanced in terms of their manufacturing sectors. It is shown that distance and thus transportation pose a problem in this type of trade between these countries. However, we need to mention that other constraints such as delays at the borders to clear goods and other administrative constraints negatively affect the penetration of these goods in the regional market.

The study also shows that in some of these countries the proportion of intra-industry trade in the bilateral trade is quite high. When we analyse the exports and imports represented in the intra-industry trade, we observe that the high ratio of intra-industry trade in bilateral trade is more evidenced with imports and exports from the smaller countries than from the relatively larger ones. In some cases the proportion of intra-industry trade is quite high even in absolute figures.

These results have important policy implications. One is that, indeed, intra-industry trade does exist in some of these countries; thus there is a need to direct attention to this trade as an adjunct of inter-industry trade. This is even more important given the ambition of these countries to further trade liberalization. As shown in the estimation, tariff barriers exert negative influence, implying that further liberalization will induce a higher level of this trade. Distance also shows a negative relationship with intra-industry trade; solving transportation problems will likely increase the trade. In general, therefore, the study points to the fact that these countries need to put more efforts into this trade by offering more incentives to traders. In addition, there is a need to increase efforts to solve the constraints to this trade, especially including transportation and communication networks. With good transportation systems, distance may be less of an obstacle to the trade. Some other factors that promote this trade are more difficult to influence, for example common borders.

## Appendix A. Results of other empirical research on intra-industry trade

---

Several empirical studies have been done in both developing and developed countries. We summarize some of them below.

### Appendix A1: Balassa, B., and L. Bauwens (1987) -Trade among developing countries

---

Variable	Measure	Coefficient	T Values

Ln T	Tariff	-0.46	(-2.25)
Ln NTB	Non tariff Barriers	-0.36	(-0.96)
N			45
R <sup>2</sup>			0.57

Countries include: India, Sri Lanka, Pakistan, Indonesia, The Phillipines, Thailand, Malaysia, Republic of Korea, Hong Kong, Singapore.

**Appendix A4: 4. Lee, H.H., and Lee, Y.Y. (1993) -intra-industry trade in manufactures: The case of Korea**

Variable	Measure	Logit analysis	Nonlinear least squares
Constant		5.639 (1.985)	0.629 (0.695)
RDPCI	Relative difference in per capita GNP	-3.872 (-1.676) (1.676)	-1.768 (-1.973) (1.973)
RDGNP	Relative difference in GNP Between Korea and Trading Partners	-3.934 (-2.729)	0.439 (0.841)
POSTAGE	Cost of postage	-1.205 (2.428)	-0.419 (2.488)
TINT	Korea's trade intensity with trading partners	17.251 (1.890)	3.932 (2.461)
ASIA	Dummy for Asian countries	2.010 (1.765)	1.261 (4.253)
TIMB	Trade imbalances	-4.608 (-3.338)	-2.136 (3.828)
DOF	Degrees of freedom	74	74
R <sup>2</sup>		0.4326	0.4235

The methods used are logit analysis and non-linear least squares. In this study zero values of IIT index were replaced with a very small number (0.0000001) so the observations could be included in the analysis.

**Table A5: Globerman S. and J.W Dean (1990) -Recent trends in intra-industry trade and their implications for future trade liberalization**

Highlights of studies of intra-industry trade.

Author	Country	Industry	Period	Main finding
Grubel, Lloyd (1975)	10 industrialized countries	All industries	1959-67	IIT as a % of total trade rose steadily from .36 to .48.
McAleese (1979)	Ireland	All industries	1964-77	IIT rose from .36 to .56.
Finger, DeRosa (1979)	14 industrialized countries	144 SITC 3 digit products	1961-76	Increase in IIT for most products.
Glejser (1979)	EEC	64 industries	1973-79	Slowness in growth of IIT compared to 1960s.
Kol, Mennes (1979)	Netherlands	9 industry group	1970-80	No general increase or decrease in IIT.
Schumacher (1979)	Germany	All industries	1962-80	Increase in IIT throughout period. Largest relative increase from 1962 to 1976.
Greenaway (1979)	UK	8 SITC divisions	1964-77	Increase in IIT for all divisions.
Greenaway, Milner (1986)	UK	9 SITC divisions	1970-79	Increase in IIT for all divisions for 1970-77. Increase for only 4 divisions from 1977 to 1979.
Balassa (1975)	EEC	All industries	1958-70	Average increase in degree of IIT of 30%
Drabek, Greenaway (1984)	EEC, Austria, Sweden, Norway, Switzerland	5 SITC divisions	1966-77	Increase in average IIT for all countries.

## Notes

---

- 1 With a Preferential Trading Area members reduce or remove impediments to trade among each other but individually retain their restrictions with the rest of the world. Over time many other developmental strategies have been adopted including monetary issues.
2. This is not a unique problem of these countries but many other empirical studies have noted this. For example, Finger and DeRosa 1978, discusses the classification difficulties with the US data. Drabek and Greenaway discusses also problems of data comparison in their study which compares The EEC and CMEA Intra-Industry Trade.
3. Hellvin 1993.

**T**he principal objective of the African Economic Research Consortium (AERC), established in August 1988, is to strengthen local capacity for conducting independent, rigorous inquiry into problems pertinent to the management of economies in Sub-Saharan Africa.

In response to special needs of the region, AERC has adopted a flexible approach to improve the technical skills of local researchers, allow for regional determination of research priorities, strengthen national institutions concerned with economic policy research, and facilitate closer ties between researchers and policy makers.

Since its establishment, AERC has been supported by private foundations, bilateral aid agencies and international organizations.

**SPECIAL PAPERS** contain the findings of commissioned studies in furtherance of AERC's programmes for research, training and capacity building.

**RESEARCH PAPERS** contain the edited and externally reviewed results of research financed by the AERC.

It is AERC's policy that authors of Special and Research Papers are free to use material contained therein in other publications. Views expressed in the Special and Research Papers are those of the authors alone and should not be attributed to the AERC's sponsoring Members, Advisory Committee, or Secretariat.

Further information concerning the AERC and additional copies of Special and Research Papers can be obtained by writing to: African Economic Research Consortium, P.O. Box 62882, Nairobi, Kenya.
